Product Analyst Assignment

Design a Leads Management Module for TalentXO

Expected effort: 8–12 focused working hours

Submission deadline: 3–4 days

About TalentXO

TalentXO operates a recruitment marketplace connecting companies hiring for open positions with a community of independent freelance recruiters, called **Talent Partners (TPs)**.

Companies share their hiring requirements on the platform. Talent Partners work on these opportunities by identifying relevant candidates, engaging with them, and submitting suitable profiles for consideration.

Multiple Talent Partners may work on the same job, while an individual Talent Partner may work on several jobs simultaneously.

What are Leads?

Alongside candidates sourced independently by Talent Partners, TalentXO maintains a database of potential candidates.

A **Lead** is a candidate profile that could be relevant to a particular open job but has not yet become an application for that position.

The purpose of the Leads module is to make better use of TalentXO's existing candidate database by connecting relevant candidate profiles with Talent Partners who can help convert them into job applications.

The platform should also have visibility into how these opportunities are being utilized and their eventual outcomes.

The Assignment

Imagine you are the Product Analyst responsible for designing the first version of TalentXO's Leads module.

Your objective is to design a SaaS workflow that enables TalentXO to distribute potential candidate leads to its Talent Partners and effectively manage their journey towards becoming job applications.

Your proposed solution should address:

- How Talent Partners can access and work with relevant candidate leads for different jobs.
- How the platform can support Talent Partners in progressing these opportunities towards successful applications.

- How users can understand the current state of their leads and identify what requires attention.
- How the platform should track progress, maintain reliable information, and handle different outcomes.

You are expected to independently define the user journey, key screens, user actions, information requirements, lead statuses, and underlying product logic.

Focus on creating a practical, end-to-end workflow for the first version of the product.

Business Problems to Solve

A shared candidate database used by multiple independent recruiters creates several operational challenges.

Consider the following situations:

1. **Overlapping efforts:** Multiple Talent Partners may want to work with the same candidate for the same job. Uncoordinated activity can create confusion, duplicate efforts, and a poor candidate experience.
2. **Unutilized opportunities:** Valuable candidate profiles may remain untouched, or a Talent Partner may begin working on a lead without making meaningful progress.
3. **Changing circumstances:** Candidate information may be incomplete or outdated. Job requirements and hiring availability may change, and candidates may progress through other recruitment channels.

These are starting points, not an exhaustive list.

Your responsibility is to identify the underlying business problems and translate them into appropriate product constraints, business rules, workflows, and edge-case handling.

Think through how the system should behave in normal and exceptional situations.

You may make reasonable assumptions wherever necessary. Explain important decisions and trade-offs.

What to Submit

1. Product Specification

Submit a document covering:

- Proposed end-to-end user journey and workflow diagrams.
- Key product screens, actions, and status transitions.
- Business problems identified and the product rules derived from them.
- Important edge cases and the system's expected behavior.
- Key assumptions and design decisions.

There is **no page limit** for the product specification. Focus on clarity, completeness, and logical reasoning.

2. Interactive Prototype

Share a clickable prototype demonstrating the primary Talent Partner experience and the important outcomes of your proposed workflow.

Use realistic mock jobs and candidate profiles.

You may use **Figma, Lovable, Bolt, ChatGPT, Claude, or any other AI/design tools** to create the prototype.

A production-ready application is not expected. Backend development, real API integrations, authentication, and persistent databases are not required.

Additional Guidance

- Focus on systems thinking, practical SaaS workflows, and business logic.
- Consider exceptions and situations where the expected workflow may not go as planned.
- Prioritize clarity and functionality over visual polish.
- Keep the solution realistic for an initial product release.

> **Submission:** Share your Product Specification and a link to your interactive prototype within 3–4 days.
